

Figure 5: Micromagnetic structures of maximally truncated octahedra, cuboctahedra and cubes. Left column (a, d, g) shows the largest SD solutions at  $d_{\rm max}$ , obtained by interpolating from solutions for smaller grains starting at 30 nm. On interpolating to a grain 2 nm larger, the structures relax to an EAV (b, e) or a distorted EAV (h) which are stable up to 120 nm. From 120 nm interpolation is carried out into smaller grains. Eventually the vortex aligns with a hard direction (c, f, i), stable down to  $d_{\rm min}$  after which the solution becomes SD again down to 30 nm. Top row (a, b, c) shows the structures for the maximally truncated octahedra; center row (d, e, f) for the cuboctahedra and bottom row (g, h, i) for the cubes. Colour represents the MCA energy normalised by  $|K_1|$ .
